

AI_ASSIGNMENT:6

Batch:12

2403A51284

Task Description #1 (Classes – Employee Management)

- Task: Use AI to create an Employee class with attributes (name, id, salary) and a method to calculate yearly salary.
- Instructions:
 - Prompt AI to generate the Employee class.
 - Analyze the generated code for correctness and structure.
 - Ask AI to add a method to give a bonus and recalculate salary.

The screenshot shows a Google Colab notebook interface with a browser window at the top displaying the URL: `colab.research.google.com/drive/1ZpHQ3IDTJRmQRqDXjH26hJck_MOPLKF#scrollTo=tlTAXSOBR0DL`. The notebook has several tabs, including 'assignment 5.4', 'Untitled2.ipynb', 'Untitled3.ipynb', 'Untitled4.ipynb', and 'Employee class review'. The active tab is 'Untitled4.ipynb', which contains the following Python code:

```
class Employee:
    def __init__(self, name, emp_id, salary):
        """
        Initialize a new Employee instance.

        :param name: Employee's name
        :param emp_id: Employee's ID
        :param salary: Monthly salary (must be non-negative)
        """
        if salary < 0:
            raise ValueError("Salary cannot be negative.")
        self.name = name
        self.emp_id = emp_id
        self.salary = salary

    def yearly_salary(self):
        """Calculate and return the yearly salary."""
        return self.salary * 12

    def give_bonus(self, bonus):
        """
        Add a bonus to the salary and recalculate yearly salary.

        :param bonus: Bonus amount to add to monthly salary (must be non-negative)
        """
        if bonus < 0:
            raise ValueError("Bonus cannot be negative.")
        self.salary += bonus
        print(f"New monthly salary after bonus: ${self.salary}")
        print(f"New yearly salary after bonus: ${self.yearly_salary()}")
```

At the bottom of the notebook, there is a 'Variables' panel and a 'Terminal' panel. The system tray at the very bottom shows the date and time as 4:00 PM on 04-09-2025, along with weather information (31°C, Partly sunny) and system icons.

```
raise ValueError("Bonus cannot be negative.")
self.salary += bonus
print(f"New monthly salary after bonus: ${self.salary:.2f}")
print(f"New yearly salary: ${self.yearly_salary():.2f}")

def update_salary(self, new_salary):
    """
    Update the employee's monthly salary.

    :param new_salary: New monthly salary (must be non-negative)
    """
    if new_salary < 0:
        raise ValueError("New salary must be non-negative.")
    self.salary = new_salary

def __str__(self):
    """Return a string representation of the employee."""
    return f"Employee(Name: {self.name}, ID: {self.emp_id}, Monthly Salary: ${self.salary:.2f})"

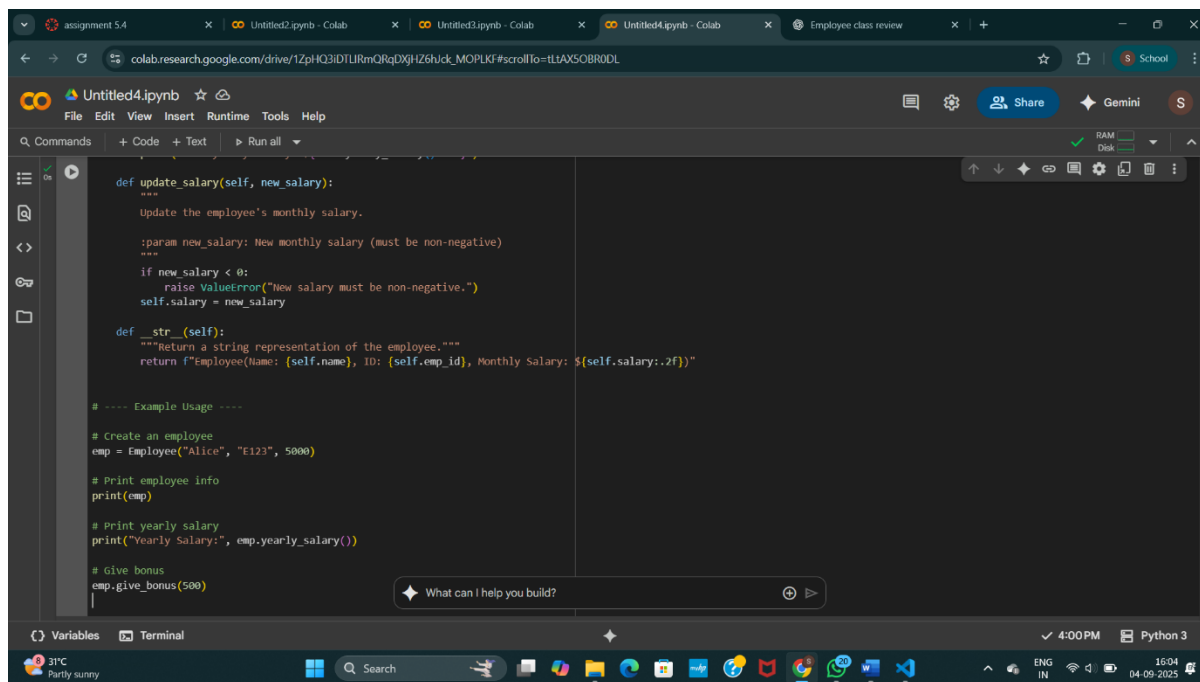

# ---- Example Usage ----

# Create an employee
emp = Employee("Alice", "E123", 5000)

# Print employee info
print(emp)

# Print yearly salary
print("Yearly salary:", emp.yearly_salary())
```

What can I help you build?

```
def update_salary(self, new_salary):
    """
    Update the employee's monthly salary.

    :param new_salary: New monthly salary (must be non-negative)
    """
    if new_salary < 0:
        raise ValueError("New salary must be non-negative.")
    self.salary = new_salary

def __str__(self):
    """Return a string representation of the employee."""
    return f"Employee(Name: {self.name}, ID: {self.emp_id}, Monthly Salary: ${self.salary:.2f})"

# ---- Example Usage ----

# Create an employee
emp = Employee("Alice", "E123", 5000)

# Print employee info
print(emp)

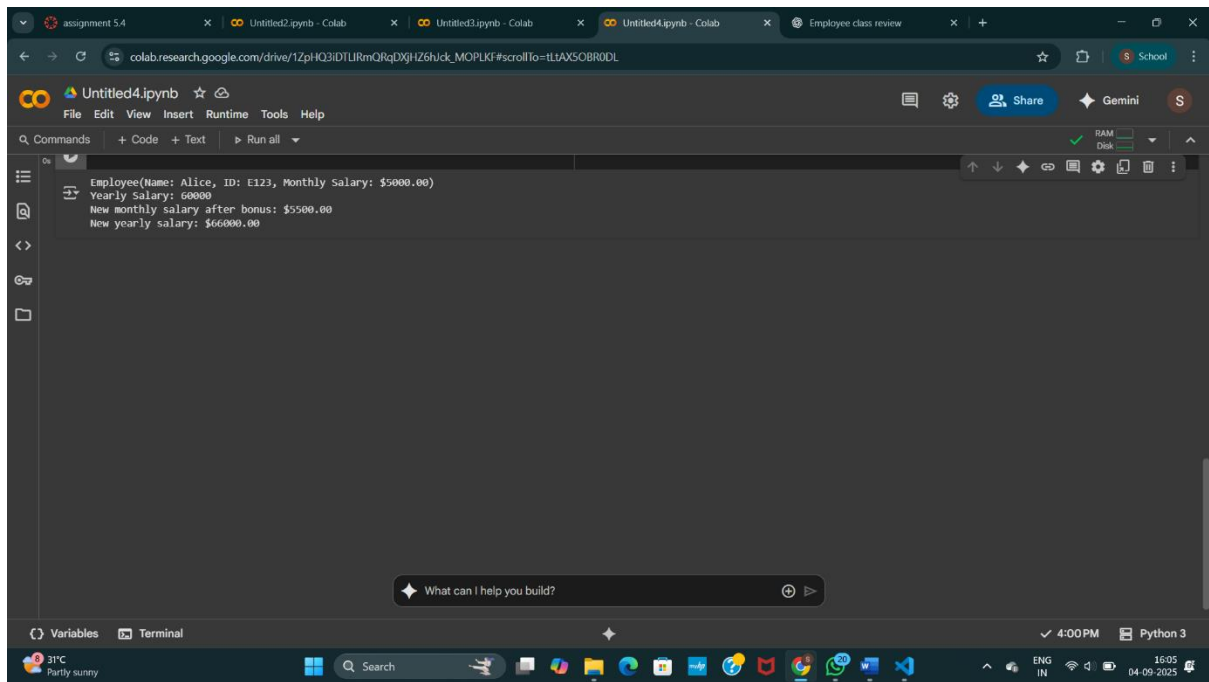

# Print yearly salary
print("Yearly salary:", emp.yearly_salary())

# Give bonus
emp.give_bonus(500)

|
```

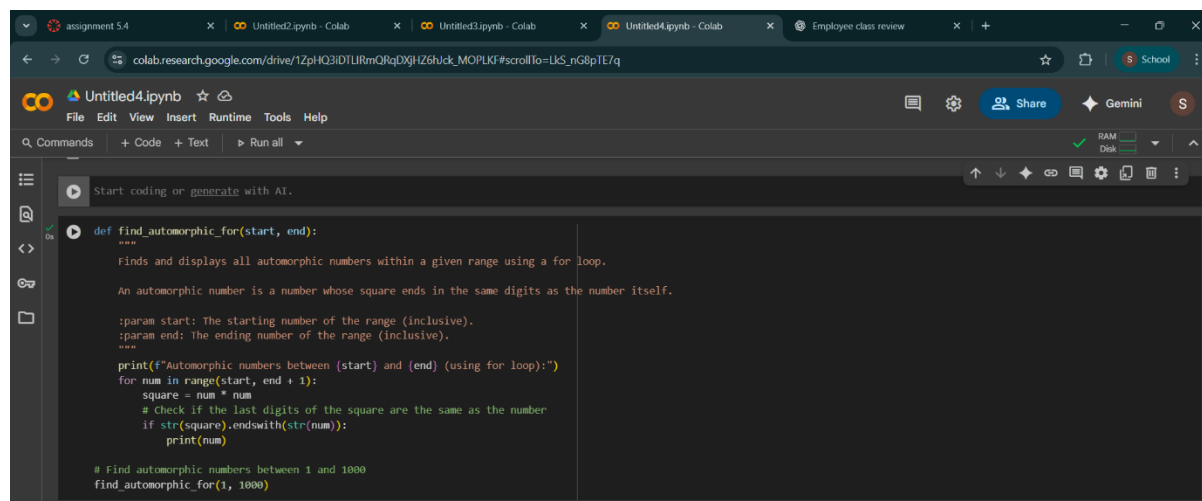

What can I help you build?

OUTPUT:

Task Description #2 (Loops – Automorphic Numbers in a Range)

- Task: Prompt AI to generate a function that displays all Automorphic numbers between 1 and 1000 using a for loop.
- Instructions:
 - Get AI-generated code to list Automorphic numbers using a for loop.
 - Analyze the correctness and efficiency of the generated logic.
 - Ask AI to regenerate using a while loop and compare both implementations.

OUTPUT:

The screenshot shows a Google Colab notebook titled 'Untitled4.ipynb'. The code cell contains a list of automorphic numbers between 1 and 1000, generated using a loop. The numbers are: 1, 5, 6, 25, 76, 376, and 625. The notebook interface includes a menu bar (File, Edit, View, Insert, Runtime, Tools, Help), a toolbar with 'Run all' and 'Share' buttons, and a status bar at the bottom showing 'Python 3' and system information.

```
Automorphic numbers between 1 and 1000 (using for loop):  
1  
5  
6  
25  
76  
376  
625
```

Task Description #3 (Conditional Statements – Online Shopping Feedback Classification)

- Task: Ask AI to write nested if-elif-else conditions to classify online shopping feedback as Positive, Neutral, or Negative based on a numerical rating (1–5).
- Instructions:
 - Generate initial code using nested if-elif-else.
 - Analyze correctness and readability.
 - Ask AI to rewrite using dictionary-based or match-case structure.

The screenshot shows a Google Colab notebook titled 'Untitled4.ipynb'. The code cell contains a function named 'classify_feedback_nested_if' that classifies online shopping feedback based on a numerical rating (1 to 5). The function uses nested if-elif-else conditions. The notebook interface includes a menu bar (File, Edit, View, Insert, Runtime, Tools, Help), a toolbar with 'Run all' and 'Share' buttons, and a status bar at the bottom showing 'Python 3' and system information.

```
def classify_feedback_nested_if(rating):  
    """  
    Classifies online shopping feedback as Positive, Neutral, or Negative  
    using nested if-elif-else conditions based on a numerical rating (1-5).  
    :param rating: An integer representing the feedback rating (1 to 5).  
    :return: A string indicating the feedback classification (Positive, Neutral, or Negative).  
    """  
    if 1 <= rating <= 5:  
        if rating >= 4:  
            return "Positive"  
        elif rating == 3:  
            return "Neutral"  
        else:  
            return "Negative"  
    else:  
        return "Invalid rating: Please provide a rating between 1 and 5."  
  
# Example Usage:  
print(f"Rating 5: {classify_feedback_nested_if(5)}")  
print(f"Rating 3: {classify_feedback_nested_if(3)}")  
print(f"Rating 1: {classify_feedback_nested_if(1)}")  
print(f"Rating 0: {classify_feedback_nested_if(0)}")  
print(f"Rating 6: {classify_feedback_nested_if(6)}")
```

OUTPUT:

The screenshot shows a Google Colab notebook interface. The top bar includes tabs for 'assignment 5.4', 'Untitled2.ipynb - Colab', 'Untitled3.ipynb - Colab', 'Untitled4.ipynb - Colab', and 'Employee class review'. The address bar shows the URL 'colab.research.google.com/drive/1ZpHQ3iDTURmQRqDXgHZ6hJck_MOPLKF#scrollTo=dd20c058'. The notebook title is 'Untitled4.ipynb'. The menu bar includes 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. The toolbar shows 'Commands', '+ Code', '+ Text', and 'Run all'. The code editor contains a single line of Python code: `print(f"Rating 6: {classify_feedback_nested_if(6)}")`. The output area displays the following text:
Rating 5: Positive
Rating 3: Neutral
Rating 1: Negative
Rating 0: Invalid rating: Please provide a rating between 1 and 5.
Rating 6: Invalid rating: Please provide a rating between 1 and 5.
The bottom status bar shows 'Colab paid products - Cancel contracts here', 'Variables', 'Terminal', '4:10 PM', and 'Python 3'.

Task Description #4 (Loops – Prime Numbers in a Range)

- Task: Generate a function using AI that displays all prime numbers within a user-specified range (e.g., 1 to 500).
- Instructions:
 - Get AI-generated code to list all primes using a for loop.
 - Analyze the correctness and efficiency of the prime-checking logic.
 - Ask AI to regenerate an optimized version (e.g., using the square root method).

The screenshot shows a Google Colab notebook interface. The top bar includes tabs for 'assignment 5.4', 'Untitled2.ipynb - Colab', 'Untitled3.ipynb - Colab', 'Untitled4.ipynb - Colab', and 'Employee class review'. The address bar shows the URL 'colab.research.google.com/drive/1ZpHQ3iDTURmQRqDXgHZ6hJck_MOPLKF#scrollTo=dd20c058'. The notebook title is 'Untitled4.ipynb'. The menu bar includes 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. The toolbar shows 'Commands', '+ Code', '+ Text', and 'Run all'. The code editor contains the following Python code:

```
def find_primes_for(start, end):  
    """  
    Finds and displays all prime numbers within a given range using a for loop.  
  
    A prime number is a natural number greater than 1 that has no positive divisors other than 1 and itself.  
  
    :param start: The starting number of the range (inclusive).  
    :param end: The ending number of the range (inclusive).  
    """  
    print(f"Prime numbers between {start} and {end} (using for loop):")  
    for num in range(max(2, start), end + 1): # Start from 2 as 1 is not prime  
        is_prime = True  
        for i in range(2, num):  
            if num % i == 0:  
                is_prime = False  
                break  
        if is_prime:  
            print(num)  
  
    # Find prime numbers between 1 and 500  
    find_primes_for(1, 500)
```

OUTPUT:

The screenshot shows a Google Colab notebook titled 'Untitled4.ipynb'. The code cell contains a Python script that prints prime numbers between 1 and 500 using a loop. The output of the code is a list of prime numbers: 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103, 107, 109, 113, 127, and 131. The notebook interface includes a menu bar (File, Edit, View, Insert, Runtime, Tools, Help), a toolbar with icons for file operations and execution, and a status bar at the bottom showing the time as 4:16 PM and the Python version as Python 3.

```
Prime numbers between 1 and 500 (using for loop):
2
3
5
7
11
13
17
19
23
29
31
37

Task Description #5 (Classes – Library System)

- Task: Use AI to build a Library class with methods to `add_book()`, `issue_book()`, and `display_books()`.
- Instructions:
 - Generate Library class code using AI.
 - Analyze if methods handle edge cases (e.g., issuing unavailable books).

Ask AI to add comments and documentation.

The screenshot shows a Google Colab notebook titled 'Untitled4.ipynb'. The code defines a `Library` class with three methods: `__init__`, `add_book`, and `issue_book`. The `__init__` method initializes an empty dictionary `self.books`. The `add_book` method adds a new book or increases the count of an existing book. The `issue_book` method checks if a book is available and issues it, decreasing the count.

```
class Library:
    def __init__(self):
        """
        Initializes an empty library with no books.
        """
        self.books = {} # Dictionary to store books: key=title, value=available_copies

    def add_book(self, title, copies=1):
        """
        Adds a book to the library or increases the number of copies if it already exists.

        :param title: The title of the book to add.
        :param copies: The number of copies to add (default is 1).
        """
        if title in self.books:
            self.books[title] += copies
            print(f"Added {copies} more copies of '{title}'. Total copies: {self.books[title]}")
        else:
            self.books[title] = copies
            print(f"Added '{title}' to the library with {copies} copies.")

    def issue_book(self, title):
        """
        Issues a book to a user if available.

        :param title: The title of the book to issue.
        :return: True if the book was issued successfully, False otherwise.
        """
        if title in self.books and self.books[title] > 0:
            self.books[title] -= 1
```

The screenshot shows the continuation of the `Library` class with a `display_books` method and example usage code. The `display_books` method prints the current state of the library. The example usage code creates a `Library` instance, adds books, and issues a book.

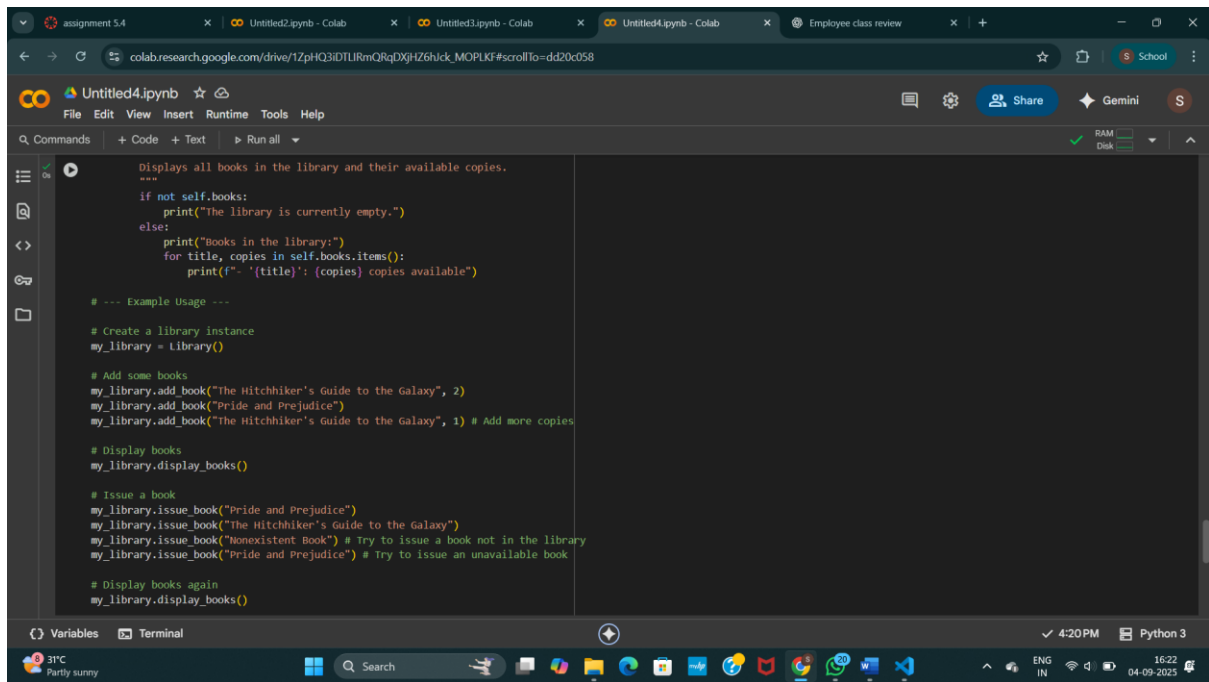

```
        if title in self.books and self.books[title] > 0:
            self.books[title] -= 1
            print(f"'{title}' issued successfully. Remaining copies: {self.books[title]}")
            return True
        elif title in self.books and self.books[title] == 0:
            print(f"'{title}' is currently out of stock.")
            return False
        else:
            print(f"'{title}' not found in the library.")
            return False

    def display_books(self):
        """
        Displays all books in the library and their available copies.
        """
        if not self.books:
            print("The library is currently empty.")
        else:
            print("Books in the library:")
            for title, copies in self.books.items():
                print(f"- '{title}': {copies} copies available")

# --- Example Usage ---

# Create a library instance
my_library = Library()

# Add some books
my_library.add_book("The Hitchhiker's Guide to the Galaxy", 2)
my_library.add_book("Pride and Prejudice")
my_library.add_book("The Hitchhiker's Guide to the Galaxy", 1) # Add more copies
```

The screenshot shows a Google Colab notebook titled 'Untitled4.ipynb'. The code defines a 'Library' class with methods to add books, issue books, and display the library's contents. The code is as follows:

```
class Library:
    """
    Displays all books in the library and their available copies.
    """
    if not self.books:
        print("The library is currently empty.")
    else:
        print("Books in the library:")
        for title, copies in self.books.items():
            print(f"  {title}: {copies} copies available")

    # --- Example Usage ---

    # Create a library instance
    my_library = Library()

    # Add some books
    my_library.add_book("The Hitchhiker's Guide to the Galaxy", 2)
    my_library.add_book("Pride and Prejudice")
    my_library.add_book("The Hitchhiker's Guide to the Galaxy", 1) # Add more copies

    # Display books
    my_library.display_books()

    # Issue a book
    my_library.issue_book("Pride and Prejudice")
    my_library.issue_book("The Hitchhiker's Guide to the Galaxy")
    my_library.issue_book("Nonexistent Book") # Try to issue a book not in the library
    my_library.issue_book("Pride and Prejudice") # Try to issue an unavailable book

    # Display books again
    my_library.display_books()
```

OUTPUT:

The screenshot shows the same Google Colab notebook, but now displaying the output of the code. The output is as follows:

```
Added 'The Hitchhiker's Guide to the Galaxy' to the library with 2 copies.
Added 'Pride and Prejudice' to the library with 1 copies.
Added 1 more copies of 'The Hitchhiker's Guide to the Galaxy'. Total copies: 3
Books in the library:
- 'The Hitchhiker's Guide to the Galaxy': 3 copies available
- 'Pride and Prejudice': 1 copies available
'Pride and Prejudice' issued successfully. Remaining copies: 0
'The Hitchhiker's Guide to the Galaxy' issued successfully. Remaining copies: 2
'Nonexistent Book' not found in the library.
'Pride and Prejudice' is currently out of stock.
Books in the library:
- 'The Hitchhiker's Guide to the Galaxy': 2 copies available
- 'Pride and Prejudice': 0 copies available
```
